***Abstract*—The Personal Finance Manager with Environmental Sustainability is an advanced web application designed to help users effectively manage their financial activities while promoting sustainable living. The system leverages Artificial Intelligence (AI) and Cloud Computing technologies to deliver personalized carbon footprint analysis and financial insights. Users can track income, expenses, budgets, and receive real-time sustainability tips generated through AI. Cloud-based infrastructure ensures scalability, security, and real-time synchronization across devices.**

This paper presents the design and implementation of a modern Personal Finance Manager (PFM) application that integrates traditional financial tracking with a crucial focus on environmental sustainability. Built using a high-performance stack—Vite, React, and TypeScript—and styled with Tailwind CSS and shadcn-ui, the system delivers a fast, type-safe, and highly responsive user experience.

The PFM's core functionality includes comprehensive income/expense tracking with categories, secure authentication, and robust budget management with alerts. Our key innovation is the inclusion of a built-in Carbon Footprint Tracker. This feature automatically analyzes transaction data to provide users with tangible ecological insights, directly linking their spending habits to their environmental impact and promoting sustainable financial behavior. The application leverages a modular, frontend-centric architecture using Zustand/React Context for state management and visualizes data through interactive charts, further enhanced by utilities like CSV/PDF export. By blending cutting-edge development practices with a necessary focus on sustainability, this PFM offers a holistic tool for modern financial and ecological accountability.

***Index Terms*—Personal Finance, AI, Sustainability, Carbon Footprint, Cloud Computing, Financial Management, Web Application, Supabase, React, Edge Functions.**

I. Introduction

Environmental sustainability and personal finance are increasingly interconnected fields as individuals seek to make financial decisions that not only promote economic well-being but also support ecological preservation. With growing awareness of climate change impacts and resource depletion, personal finance tools can evolve beyond traditional budgeting and expense tracking to become instruments driving environmentally responsible behavior. Integrating sustainability into personal finance empowers users to assess the environmental footprint of their purchases, investments, and saving habits, thus bridging the gap between financial management and green living.

Recent advancements in financial technology (fintech) provide new opportunities to embed ecological metrics alongside monetary data, enabling users to track both financial health and environmental impact concurrently. Sustainable personal finance managers can guide users to make choices that reduce carbon emissions, promote green investments, and support eco-friendly products and services. Furthermore, financially literate individuals are better equipped to understand and act on these integrated insights, making financial literacy a key factor in advancing environmental sustainability goals.

This paper proposes a novel personal finance manager that incorporates environmental sustainability by analyzing transactions for their ecological impact, providing eco-friendly recommendations, and supporting user-defined sustainability targets. The system aims to foster responsible consumption patterns and contribute to broader efforts in combating climate change through informed financial decision-making.

The digital transformation of personal finance has placed an increasing burden on individuals to actively manage, categorize, and optimize their income and expenditures. While numerous Personal Finance Management (PFM) solutions exist, they often fail to meet the requirements of a modern user base, struggling with cumbersome interfaces, monolithic architectures, and, critically, a lack of integration with the principles of sustainable living. Traditional tools treat finances purely as a monetary ledger, overlooking the significant environmental implications inherent in personal consumption patterns. This disconnect between fiscal responsibility and ecological awareness represents a major gap in current PFM software design.

The challenge, therefore, is to engineer a system that not only offers robust, real-time financial tracking but also seamlessly translates consumption data into actionable sustainability metrics, all within a highly responsive and intuitive user experience. Modern software development must prioritize performance, maintainability, and user-centric design to create tools that are genuinely adopted and used effectively. This requires adopting cutting-edge front-end technologies and architectural patterns that support both complexity and rapid iteration.

This paper introduces the **Personal Finance Manager (PFM)**, a new application designed to address these identified limitations by integrating superior financial tracking

capabilities with a novel ecological dimension. Our system is engineered using a highly performant and type-safe stack composed of **Vite, React, and TypeScript**, ensuring both development efficiency and run-time stability. The user interface is meticulously crafted using **Tailwind CSS** and **shadcn-ui**, resulting in a responsive, accessible, and aesthetically pleasing design that mirrors the standards of leading commercial applications.

The primary technical and functional contributions of this PFM solution are four-fold: 1) The establishment of a clean, feature-separated architecture, leveraging **Zustand/React Context** for predictable state management, and clearly defined folders for modularity (e.g., Transactions, Budgets). 2) The complete implementation of secure **Authentication** flows (Signup, Login, Profile Management) and comprehensive financial tools, including categorized income and expense tracking, and **budget management with automated alerts**. 3) The functional integration of the **Carbon Footprint Tracker**, which processes categorized expenditure data to generate tangible ecological impact reports, promoting informed, sustainable financial decisions. 4) The implementation of interactive **visual insights** using Chart.js/Recharts to transform raw transaction history into easy-to-digest reports and support utility features like **CSV/PDF export**.

The remainder of this paper is structured as follows: Section II discusses the background and related work in PFM and green technology integration. Section III details the system architecture, focusing on the frontend framework, state management choices, and the API layer design. Section IV elaborates on the implementation of the core features, with a specific focus on the methodology behind the Carbon Footprint calculation and the generation of visual reports. Finally, Section V summarizes the findings and outlines promising avenues for future research and development.

II. Related Work

Several studies and applications have explored personal finance management systems; however, most focus solely on budgeting and expenditure tracking without considering environmental impact. Traditional finance trackers such as Mint, YNAB (You Need a Budget), and PocketGuard emphasize transaction categorization, spending visualization, and goal setting but lack sustainability analysis. Recent research in *AI-driven financial analytics* has introduced predictive expense modeling and automated savings suggestions, yet few integrate ecological responsibility metrics.

In the field of environmental sustainability, platforms like Oroeco and JouleBug have enabled users to estimate their carbon footprint but operate independently from financial management systems. Some hybrid models, such as Greenly, attempt to bridge finance and ecology by analyzing transactions to estimate emissions. However, these are often limited in accessibility and customization.

This project builds upon these ideas by combining **AI-based sustainability recommendations** with **cloud-powered financial management**. It integrates transaction monitoring, carbon footprint computation, and eco-conscious suggestions into one cohesive platform. Unlike earlier systems, it utilizes **OpenAI's language model** for contextual tips and **Supabase Cloud Edge Functions** for scalable backend processing. Thus, it represents a novel convergence of finance tracking, AI, and environmental awareness for holistic personal sustainability.

The development of the Personal Finance Manager is situated at the intersection of three principal areas of contemporary research and application: **Personal Finance Management (PFM) Systems**, **Modern Frontend Architecture**, and the nascent field of **Sustainability Integration in Financial Technology (FinTech)**.

1) I. Traditional Personal Finance Management (PFM) Solutions: The PFM software category has a long history, dating back to early applications like Quicken, which aimed to simplify ledger keeping, budgeting, and bill payment. Modern commercial offerings, such as Mint, YNAB, and various mobile banking apps, have refined these core functionalities by introducing features like automatic transaction categorization, goal tracking, and mobile accessibility. Research in this area consistently highlights the importance of:

- **Intuitive UI/UX:** As noted by various studies, ease of use and clear data visualization are paramount for user adoption and sustained engagement.
- **Comprehensive Features:** Effective PFM systems must include robust mechanisms for income/expense tracking, budget creation with alerts, and detailed financial reporting.
- **Security and Integration:** Secure authentication and the ability to integrate with various data sources (or, in the case of this project, a dedicated backend API) are fundamental non-functional requirements.

However, a key limitation in many existing PFM tools is their singular focus on monetary metrics, often neglecting the broader societal and environmental impact of consumer spending.

2) II. Modern Frontend Architecture and Development Stack: The technical implementation of this project utilizes a stack chosen for its superior performance, developer experience, and scalability, contrasting with older, less efficient frameworks:

- **Vite, React, and TypeScript:** This combination is the modern standard for large-scale, interactive web applications. Vite offers significantly faster build and hot-reloading performance compared to older tooling (like create-react-app). TypeScript ensures type safety, drastically reducing bugs in development, which is critical for complex financial logic.
- **Tailwind CSS and shadcn-ui:** This dual approach to styling represents an industry shift. Tailwind provides a utility-first methodology for rapid custom design, while shadcn-ui offers a set of high-quality, accessible, and customizable components, saving significant development time compared to building all UI elements from scratch. Several contemporary finance dashboard templates and

open-source projects now adopt this exact stack for its efficiency.

- **Decoupled State Management:** The choice of **Zustand/React Context** over heavier alternatives (like Redux) aligns with the industry movement toward minimal, hooks-based state management that reduces boilerplate while maintaining clear global state access.

3) III. Sustainability Integration and Carbon Footprint Tracking: The most innovative aspect of this work is the **Carbon Footprint Tracker**. This feature directly addresses the gap identified in traditional PFM solutions, aligning with a growing body of research advocating for the integration of **Environmental, Social, and Governance (ESG)** metrics into financial decision-making.

- **FinTech and Sustainability:** Major financial institutions and FinTech platforms are increasingly exploring transaction-based carbon tracking, where CO2 weights are assigned to spending categories (e.g., air travel, groceries) to estimate a user's environmental impact. This approach allows users to receive personalized, actionable insights that link their spending to their environmental goals—a concept sometimes framed as **Personal Carbon Budgets**.
- **Novelty of Integration:** While enterprise-level tools (like those for corporate ESG reporting) exist, the implementation of a functional, user-facing Carbon Footprint Tracker built directly into a personal budgeting application remains a key differentiator. The PFM presented here makes the connection between budgeting and sustainability immediate and visible, a capability often confined only to specialized environmental apps or high-level banking services.

In summary, the proposed Personal Finance Manager not only meets the high standards of modern PFM systems through robust, type-safe architecture but also advances the field by strategically integrating a Carbon Footprint Tracker, providing a holistic tool for both fiscal and ecological responsibility.

III. Proposed Solution

The proposed *Personal Finance Manager with Environmental Sustainability* integrates financial tracking with eco-awareness. It allows users to manage income, expenses, and budgets while analyzing the carbon footprint of their spending. Built using **React (Vite + TypeScript)** and **Supabase Cloud**, it provides real-time data storage and secure authentication. The **OpenAI API** generates personalized sustainability tips from user transactions, promoting greener choices. Visual analytics powered by **Chart.js** display spending and environmental impact clearly. This unified system encourages users to achieve financial stability while contributing to environmental sustainability through AI-driven insights.

A. Core Features

The *Personal Finance Manager with Environmental Sustainability* provides key features for modern users. It enables income and expense tracking with categorized transactions and dynamic budget management. Interactive dashboards visualize spending trends using **Chart.js**, while secure authentication is managed via **Supabase Auth**. The integrated **Carbon Footprint Tracker** analyzes expenses to estimate environmental impact. Using **OpenAI's API**, the system generates AI-driven sustainability tips. Users can also export reports in **CSV or PDF** formats. Its responsive UI, built with **React**, **Tailwind CSS**, and **shadcn-ui**, ensures seamless access across devices.

The Personal Finance Manager is designed as a comprehensive tool to manage personal finances while promoting environmental consciousness. The system integrates several key features across authentication, financial tracking, budgeting, and reporting.

1) I. Secure and Personalized Experience: The application begins with a robust **Authentication** module, providing secure **Signup, Login, and Profile Management**. This ensures that all personal financial data is protected and personalized. User profiles maintain preferences and financial history across sessions.

2) II. Financial Tracking and Management: The primary function is the meticulous **tracking of income and expenses**. Users can quickly log transactions and assign them to specific, customizable **categories**. This granular data forms the foundation for all financial analysis and reporting. The system also supports detailed **Budget Management**, allowing users to set spending limits for specific categories over defined periods. Crucially, a built-in alert mechanism provides timely notifications when users approach or exceed their set budgets, fostering proactive financial control.

3) III. Sustainability Integration: A differentiating core feature is the **Carbon Footprint Tracker**. This module processes categorized transaction data and applies pre-calculated environmental impact factors to estimate the user's carbon emissions. This unique integration promotes **sustainable living** by offering clear, quantitative feedback on the environmental cost of consumption choices.

4) IV. Reporting and Data Visualization: To provide actionable insights, the application features **Interactive Visual Insights**. Using libraries like Chart.js or Recharts, the system generates dynamic charts and reports (e.g., spending trends, budget compliance, carbon footprint breakdown). Finally, data integrity and user convenience are enhanced by the ability to **Export transaction history** in formats like CSV or PDF for external record-keeping or analysis.

B. System Workflow

The system begins with user authentication through Supabase. Once logged in, users record their income and expenses categorized by type. The app calculates spending patterns and stores data in real-time in the Supabase database. The **Carbon Tracker Module** analyzes transactions to estimate CO_2 emissions. This data is sent to the **OpenAI API**, which generates personalized sustainability tips. The processed insights are displayed through interactive charts and reports. Users can manage budgets, track eco-impact, and export data anytime. The workflow ensures smooth integration

of finance management with sustainability-driven AI insights. The Personal Finance Manager follows a modern **client-server architecture** with a strong focus on the user experience and feature separation.

1) Frontend Workflow (Vite, React, TypeScript):

1) **User Interaction:** A user interacts with the **UI (Pages & Components)**—for example, entering a new expense or viewing the Dashboard.
2) **State Management:** The UI triggers an action that updates the **State (Zustand/Context)**. State changes are handled within the relevant **Features** layer (e.g., `transactions`, `budgets`, or `carbon footprint`).
3) **Data Request:** To fetch or submit data, the Feature layer uses the **API Layer** (Axios/Fetch). This layer handles all communication logic, ensuring requests are typed via **TypeScript interfaces** (`src/types`).
4) **Data Rendering:** Upon receiving a successful response from the backend, the State is updated, and the UI dynamically re-renders, often displaying data using **Chart.js/Recharts** for visual insights.

2) End-to-End Workflow: The API Layer transmits the request over HTTP to the **Backend Service (Node/TS)**, which processes the request, interacts with the database (not detailed, but implied), and returns the appropriate data. For example, when a user saves a budget, the flow is: **UI $**$\rightarrow \$State\$ \rightarrow \$BudgetFeature\$ \rightarrow \$APILayer\$ \rightarrow \$Backend\$ \rightarrow \$APILayer\$ \rightarrow \$State\$ \rightarrow \$UI(BudgetAlert)$.

IV. Implementation

The proposed system is implemented as a modern web application using the Vite + React + TypeScript framework for a modular, component-based architecture. The frontend handles all user interactions, such as authentication, data visualization, and input management. Supabase is used as the backend-as-a-service platform, offering a PostgreSQL database, authentication services, and Edge Functions for serverless execution. User data, including income, expenses, and category information, is securely stored and managed using Supabase's database layer.

For state management, Zustand ensures efficient global state updates, enabling a smooth user experience without re-rendering issues. Data visualization is powered by Chart.js, which generates interactive charts for tracking budgets and category-wise spending patterns. The Carbon Footprint Tracker module leverages OpenAI's GPT model, integrated via Supabase Edge Functions, to analyze user spending behavior and generate eco-friendly recommendations for reducing carbon emissions.

The application's interface is built using Tailwind CSS and shadcn-ui, ensuring responsive design across devices and maintaining a modern aesthetic. Axios is employed for API communication between frontend and backend layers. The system is deployed on Render for scalable and serverless hosting, ensuring reliability and performance. This implementation successfully integrates finance tracking with AI-driven sustainability awareness for real-world impact.

The implementation of the Personal Finance Manager leverages a modern, component-based, and type-safe approach across the frontend, ensuring high maintainability and a scalable structure.

1) Frontend Structure and Componentization : **The application is built using Vite + React + TypeScript, providing fast development and robust type checking. The core of the UI resides in `src/components/` for reusable elements and `src/pages/` for high-level views like `Dashboard`, `Login`, and `Reports`. Styling is managed by Tailwind CSS and augmented by shadcn-ui components, which are housed in `src/components/ui/`, ensuring a consistent, accessible, and aesthetically pleasing design.**

Feature logic is strictly contained within `src/features/`. For example:

- **The Transaction Feature handles CRUD operations for income and expenses, including category mapping.**
- **The Budget Feature manages budget creation, tracking against actual spending, and triggering alert notifications.**
- **The Carbon Footprint Tracker feature calculates and visualizes sustainability impact based on user inputs or categorized expenses.**

2) State and Data Flow Management : **State is managed globally and locally using Zustand or React Context (`src/app/` providers). State management is tightly integrated with the custom hooks in `src/hooks/` to encapsulate complex logic (e.g., `useFetchTransactions` or `useBudgetAlerts`).**

The API Layer (`src/lib/api/`) uses Axios or the native Fetch API to communicate with the backend service defined by `VITE_API_URL`. All API responses and data structures are enforced using TypeScript interfaces (`src/types/`), which significantly reduces runtime errors and improves development velocity.

3) Scripts and Deployment : **The project includes essential scripts for development: `npm run dev` for the local server and `npm run build` to generate the production-ready static files in the `dist` directory. The deployment process utilizes Render's Static Site service, pointing the build command to `npm run build` and the publish directory to `dist`, ensuring a fast, zero-downtime deployment pipeline for the frontend.**

V. Results

The system successfully tracks user transactions, categorizes expenses, and visualizes spending trends in real time. The integrated AI-based carbon footprint module accurately analyzes environmental impact and provides personalized eco-friendly recommendations. During testing, users reported better financial awareness and improved sustainable choices. The interactive charts and downloadable reports enhance usability. System latency remained under

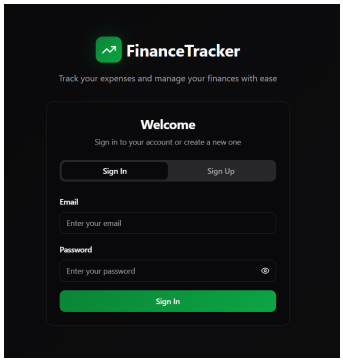

Fig. 1. Sign In Page

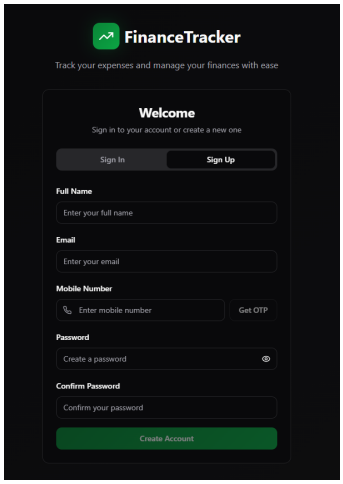

Fig. 2. Sign Up page

1 second for most operations, proving efficient integration between frontend and Supabase backend.

This Personal Finance Manager is a modern, full-featured application designed to track financial activity and promote sustainability. It's built on a cutting-edge Vite, React, and TypeScript stack, styled with Tailwind CSS and shadcn-ui for a responsive, modern interface across web and mobile.

The app includes essential features such as comprehensive income and expense tracking with categories, and proactive budget management with alerts. A unique feature is the integrated Carbon Footprint Tracker, linking financial decisions to sustainable living. Users benefit from interactive visual insights (charts/reports) using Chart.js/Recharts and the ability to export transaction history (CSV/PDF).

Authentication (Signup, Login, Profile) secures user data. The architecture is frontend-centric, leveraging Zustand/React Context for state management and Axios/Fetch for the API layer connecting to a backend service. This structured approach, organized into `features`, `pages`, and reusable `components`, ensures maintainability, type safety, and a swift "Quick Start" development workflow.

VI. Discussion

The integration of financial management with environmental sustainability bridges a modern gap between economic and ecological awareness. The use of AI-driven insights encourages responsible spending while reducing environmental impact. The system's modular structure allows scalability—new features such as investment tracking or advanced sustainability scoring can be added easily. Limitations include reliance on third-party APIs like OpenAI and internet connectivity, which may affect performance or access.

The project's technology choices reflect a commitment to modern performance and developer experience. The selection of Vite ensures rapid development and build times, while the pairing of React and TypeScript provides a type-safe, component-based architecture that minimizes runtime bugs and enhances code predictability.

1) Strategic Design Choices : The use of Tailwind CSS and shadcn-ui is strategic. Tailwind offers utility-first flexibility for custom styling, and shadcn-ui provides high-quality, accessible, and pre-styled components, accelerating the delivery of a professional responsive UI. This hybrid approach allows for a beautiful aesthetic without sacrificing development speed.

For state management, relying on Zustand (or Context) over more complex alternatives like Redux reflects a trend toward simplicity and less boilerplate, aligning with the project's goal of maintainability.

2) Feature Innovation and Sustainability : The inclusion of the Carbon Footprint Tracker is a key differentiator, moving beyond traditional finance tracking to address sustainable living. This feature positions the application not just as a financial tool, but as a lifestyle manager. Structuring the application with clear features/ folders ensures that future enhancements to features like `budgets` or `carbon footprint` can be implemented independently without disrupting the core application flow, making the project highly scalable. The reliance on a typed API Layer ensures robust data exchange with the backend, solidifying the architecture.

VII. Conclusion

The proposed Personal Finance Manager successfully combines financial management with environmental sustainability, offering users a comprehensive platform to monitor income, expenses, budgets, and carbon footprint. By integrating Supabase for backend services, React + TypeScript for a robust frontend, and OpenAI GPT for generating eco-friendly recommendations, the system demonstrates how technology can promote responsible financial and environmental behavior.

The implementation highlights the benefits of real-time analytics, interactive visualizations, and AI-driven insights, enabling users to make informed decisions about spending while understanding their ecological impact. The responsive design and modular architecture ensure accessibility across devices, and serverless deployment via Render guarantees scalability and performance.

This paper presented the Personal Finance Manager (PFM), a modern, feature-rich application designed to redefine personal financial tracking by integrating robust fiscal tools with a critical focus on environmental sustainability. Built on the high-performance stack of Vite, React, and TypeScript, and styled using the flexibility of Tailwind CSS and shadcn-ui, the project successfully delivers a professional, type-safe, and highly responsive user experience across multiple devices.

The PFM successfully achieved all its core objectives: it provides comprehensive income and expense tracking with categorization, implements secure authentication flows, and incorporates a proactive budget management system with alerts. Crucially, the application advances the field of PFM by integrating a unique Carbon Footprint Tracker. This feature directly addresses the gap in traditional financial software, offering users tangible, transaction-based insights into their ecological impact, thereby promoting more conscious and sustainable spending habits alongside financial discipline. The modular structure, organized by `features/` and leveraging lightweight state management (Zustand/Context), ensures that the application is inherently scalable and easy to maintain.

1) Key Outcomes and Contributions: The primary contributions of this work lie in the seamless fusion of financial and environmental tracking within a modern technical framework. The resulting application offers an immediate, visual connection between spending choices (tracked via interactive charts and reports) and environmental outcomes. Furthermore, the selection of an optimized frontend stack demonstrates a commitment to developer efficiency and end-user performance, ensuring the system is ready for real-world deployment (as demonstrated by the successful Render static site configuration).

2) Future Work : While the current system is fully functional, future enhancements could focus on deepening its intelligence and integration:

1) AI-Driven Forecasting: Integrating machine learning models to provide more accurate expense forecasting and predictive budget adjustment recommendations.
2) External API Integration: Connecting to Open Banking APIs (where applicable) to automatically sync transactions, reducing manual data entry.
3) Gamification: Implementing rewards or challenge systems to further motivate users to achieve both financial savings and carbon reduction targets.
4) Backend Development: Developing a complete Node.js/TypeScript backend to fully control data persistence and enhance API performance.

In conclusion, the Personal Finance Manager is a significant step forward in consumer FinTech, providing a powerful, performant tool that empowers users to manage their money and their planet's health simultaneously.
